Okay, so the things you're going to need to know are the design systems, yes, just have familiarity with what they look like, why they're important, this is just high level, but when to use them, what makes them, what makes like a design system good versus bad, and also the governance part, know about like managing a design system, and then, so obviously Figma is key, so you've used Figma a lot, you're going to want to know about like theming and tokening, so those are like automating and Figma, whatever you can, so theming and tokening are important because you can set themes for like specific color palettes and styles, tokens, the tokens are like give you the themes, but then you could also be able to set certain styles for certain like screen sizes, so like automating as much as you can in Figma is important, so like finding faster processes, standardizing, design systems are basically there to standardize, talk about the accessibility part of design systems, and like testing, what is it called, yeah, like testing components is what they're called, in order to make sure they're accessible and work at all screen sizes, and what was another thing I was, stress testing is what it's called, and then, I forgot the other thing, dark mode, light mode design systems, so having both, and then start looking into cloud code and building design systems, so try one on your own, probably just take you an hour to build, watch a video, this is using cloud code to build a design system in Figma, and you could create your own example, tweak it, and put it on your portfolio, you'll be done in two hours, I promise, yeah, but the thing is, is that if you could show, I did this in two hours, here's my, the quality of my work, and that would be a good portfolio, because you could work on I do that like a lot for, yeah, I'll show you, go ahead, very good, so that would be a good one, but yeah, everyone's integrating cloud code in Figma right now, so just watch videos about that, do, if you have tokens, practice, practice what you can do with that, design systems are great, because you could ask Claude to like, hey, use this design system, I'm linking you to the library, and create me a page that, and then, and then can it look similar to this one, and then it uses your components to create pages, so there's a lot of automation with that right now, I mean, it's not perfect, but it's a good start, and for brainstorming, right, so those are key, mobile versus desktop design, so for web, that would be good, apps and mobile, and mobile web follow similar rules, so you should be good with that, and then, yeah, I think from there, it depends on what you're applying for, so like, if you're applying for it, yeah, so like, I mostly worked in like, you know, front-end commercial, so if it's something like that, like, like selling a product, have you ever done like, like a white label kind of thing, a what, white label, do you know what that is, you know, like, um, Expedia, you know, like a travel website, you know, a workplace, yeah, so workplace, you know, how they have, like, they create everything for all these different, like, third parties, so it's like, apply for this job through this job, you know what I'm saying, oh yeah, like, SaaS, the software as a service, basically, yeah, so, so that's what, like, white labeling is, just like, changing it up for, like, other businesses, like, have you ever worked on something like that, or do you have suggestions with that, have I worked at something like that, or any, like, knowledge, no, I don't think I have, to be

honest, um, I think I did a project with the company, but it wasn't about that, though, I mostly done commercial sites, so that's my experience in using it for commercial sites, like, uh, I know Lily makes apps and stuff, so their design system is meant to work for both mobile, desk, like, mobile and desktop web, and then, um, applications, so it needs to be robust enough to be able to work Android, iOS, et cetera, so, um, keep, yeah, yeah, and mobile phone, yeah, um, so keep that in mind, but I think, yeah, design systems are the biggest thing right now, and if you're a new user experience researcher, you might be doing some research on design systems, I'm sure, um, so that's a big one, and then, like I said, the, using tokens and themes and variables and booleans and, um, uh, Figma, oh, and rapid prototyping using Cloud, so I think you've already done some of that, um, look up how to, like, yeah, so, so, definitely see, um, you know, talk about how you've done rapid prototyping, your process, practice talking about that. I just did one for a startup, so a little bit in, like, four hours, so. Yeah, yeah, so that's perfect, so say, in four hours, I was able to do this, do this, this, and this by doing this, this, and this.

From, like, and I think the, the biggest thing for me, too, is, like, with, like, context, because, like, with my, with the startup thing, I did it with not knowing what the product was from, like, like, literally from meeting the stakeholder to, like, literally finish product in, like, I said, like, four hours. Okay, yeah, but, yeah, I mean, there's nothing else, that's fine, I'll just, yeah. So, variants, so auto layout in Figma is just it stacking it the way it does on mobile, you just stack it from top to bottom, and it'll react the way it does on mobile, you know, because, like, as you add divs, they stack to the bottom, that's the exact same way auto layout works, and that's how it shows up in your frames in Figma, so auto layout's the way to go, I, it's really looked down upon if you don't use auto layout, so definitely learn how to use that, and then, um, variants are, like, when you create components, these are important for design systems, because you need to be able to create, um, like, for example, like, let's say you have the rectangle, and then you want, you want two versions of it, you want it to be red, and then green sometimes, right, so you create a variant, or it's, like, it's the same rectangle, and then, um, you say, uh, create variant, and then, um, one is green, one is red, and then you toggle, like, uh, you set the color, you put, uh, in the field, the property field color, and then a drop down shows green and red, and then you can switch between the two, and you can add a blue one, so you just duplicate one of your squares, and make it a blue color, and then give it the property blue, and then, but that's how design systems work, because you add all these elements, like, um, like, uh, show label, show chip, um, like, an accordion, expanded or not expanded, like, yes or no, like, on and off, so that adds that extra, like, customized, like, like, it allows you to customize your design systems, or, like, components without someone having to detach and customize, because ideally, you don't want anyone detaching from your design system, you want everyone to use those components, and use them with all the features they have, because it has to be one-to-one with your web-made components, like, in React or something, right, which that's what most people are using right now to make components is React, yeah, so, um, uh, so they have to match one-to-one, so you don't want someone using your component detaching, because you don't have a certain feature, like, customized, like, variant, right, and then they, like, make their own thing, and then you're like,

hey, I can't do that, like, our library on React doesn't let us make the accordion purple, or, like, you know, or have those, or have nine chips, we can only have one chip, like, you want to be able to give them flexibility in your design system, but, um, you know, but you also want to give them limitations, or else they're going to start going crazy with the designs, they're going to look bad, like, you want to make sure no matter what they do within those parameters of the variants, um, they have flexibility, but also, um, you limit them, so that no matter what they put out there, it still wouldn't look good, if that makes sense, so it's like a, it's like a, it's balancing, like, how much, you know, but, uh, how much you can do, um, but that's what, um, Amy does, she's the product owner of the Lilly design system, so she, like, runs the, um, she's in charge of overseeing, like, the changes to the design system, who's using it, um, so that's what, like, her role is, and then, but then there, uh, but then there are designers who are designing the variants, like, the different toggles, like, how you can customize, like, text, how you customize, like, a full-width hero, or a banner, or something, and then you have the dev people putting it into code, and, um, creating, like, libraries for it online.

I also mentioned, um, Amy, and when I reached out to her role. Oh, okay. I don't know if she and Lilly know each other any well, but...
